Introduction
Diagnostic laparoscopy with biopsy is a useful tool in the diagnosis and staging of abdominal conditions, such as gastric cancer [1,2]. The biopsied tissue should be retrieved and sent to the laboratory in the best conditions, avoiding excessive crushing and lymph node biopsy should provide the whole intact node. To reduce pain and wall complications it would be preferable that the operative ports are 5mm or less. Unfortunately, retrieving a tissue specimen through a small port makes it to be crushed and often not suitable to be analyzed. Moreover, no 5mm laparoscopic bag is commercially available and there is the risk of tumour seeding if the tissue is extracted without a bag. One should use a 10mm trocar to retrieve the specimen in a bag, but this increases invasiveness and costs of the operation. Surgical gloves have been used to retrieve even huge specimens in laparoscopic surgery [3] (Figure 1).

Technique
The operation is conducted with one 10-12 mm port for the camera and 2 operative 5 mm trocars. The tissue to be analysed is dissected off and held with a grasper. The middle finger of a powder-free size 8.5 or 9 surgical glove is cut off obliquely and a 1/0 silk stitch is double passed and tied at the open edge, leaving the whole length of the tie. The device is inserted into the abdomen through the camera port leaving the free end of the tie hanging out. The camera is reinserted and the specimen is put into the glove. The glove is subsequently brought out by pulling on the tie. If necessary, the trocar can be extracted along with the specimen.

Discussion and Conclusion
After a successful trial with laparoscopic appendicectomy [4], at the moment we are applying this technique also for diagnostic laparoscopy. Our technical trick can be useful to retrieve small specimens through the umbilical port, under camera control, without damaging the tissue and disrupting cancer cells.
